# Probability: <br> Reasoning Under Uncertainty 

## CS171, Fall Quarter, 2018 Introduction to Artificial Intelligence <br> Prof. Richard Lathrop

Read Beforehand: R\&N 13

University of California

## outine

- Representing uncertainty is useful in knowledge bases
- Probability provides a coherent framework for uncertainty
- Review of basic concepts in probability
- Emphasis on conditional probability \& conditional independence
- Full joint distributions are intractable to work with
- Conditional independence assumptions allow much simpler models
- Bayesian networks (next lecture)
- A useful type of structured probability distribution
- Exploit structure for parsimony, computational efficiency
- Rational agents cannot violate probability theory

## Uncertainty

Let action $A t=$ leave for airport $t$ minutes before flight Will $A t$ get me there on time?

Problems:

1. partial observability (road state, etc.)
2. multi-agent problem (other drivers' plans)
3. noisy sensors (uncertain traffic reports)
4. uncertainty in action outcomes (flat tire, etc.)
5. immense complexity of modeling and predicting traffic

Hence a purely logical approach either

1. risks falsehood: "A25 will get me there on time", or
2. leads to conclusions that are too weak for decision making:
"A25 will get me there on time if there's no accident on the bridge and it doesn't rain and my tires remain intact, etc., etc.
"A1440 should get me there on time but I'd have to stay overnight in the airport."

## Uncertainty in the world

- Uncertainty due to
- Randomness
- Overwhelming complexity
- Lack of knowledge
- ...
- Probability gives
- natural way to describe our assumptions
- rules for how to combine information
- Subjective probability
- Relate to agent's own state of knowledge: P(A25|no accidents)= 0.05
- Not assertions about the world; indicate degrees of belief
- Change with new evidence: $\mathrm{P}(\mathrm{A} 25 \mid$ no accidents, 5 am$)=0.20$

## Propositional Logic and Probability

- Their ontological commitments are the same
- The world is a set of facts that do or do not hold

Ontology is the philosophical study of the nature of being, becoming, existence, or reality; what exists in the world?

- Their epistemological commitments differ
- Logic agent believes true, false, or no opinion
- Probabilistic agent has a numerical degree of belief between 0 (false) and 1 (true)

Epistemology is the philosophical study of the nature and scope of knowledge; how, and in what way, do we know about the world?

## Making decisions under uncertainty

- Suppose I believe the following:
- P(A25 gets me there on time | ...) $=0.04$
- $P($ A90 gets me there on time | ...) $=0.70$
- $\mathrm{P}(\mathrm{A} 120$ gets me there on time $\mid . .)=$.
- $P($ A1440 gets me there on time | ...) $=0.9999$
- Which action to choose?
- Depends on my preferences for missing flight vs. time spent waiting, etc.
- Utility theory is used to represent and infer preferences
- Decision theory= probability theory + utility theory
- Expected utility of action a in state s

$$
=\sum_{\text {outcome in Results }(s, a)} P \text { (outcome) * Utility(outcome) }
$$

- A rational agent acts to maximize expected utility

## Example: Airport

- Suppose I believe the following:
- P(A25 gets me there on time | ...) $=0.04$
- $P($ A90 gets me there on time $\mid$... $)=0.70$
- $\mathrm{P}(\mathrm{A} 120$ gets me there on time $\mid . .)=$.
- $P($ A1440 gets me there on time | ...) $=0.9999$
- Utility(on time) $=\$ 1,000$
- Utility(not on time) $=-\$ 10,000$
- Expected utility of action a in state $s$

$$
=\sum_{\text {outcome in Results }(s, a)} P(\text { outcome }) * \text { Utility(outcome) }
$$

$E($ Utility $(\mathrm{A} 25))=0.04 * \$ 1,000+0.96 *(-\$ 10,000)=-\$ 9,560$
$E($ Utility $($ A90 $))=0.7^{*} \$ 1,000+0.3 *(-\$ 10,000)=-\$ 2,300$
$\mathrm{E}($ Utility $(\mathrm{A} 120))=0.95 * \$ 1,000+0.05 *(-\$ 10,000)=\$ 450$
$E(U t i l i t y(A 1440))=0.9999 * \$ 1,000+0.0001 *(-\$ 10,000)=\$ 998.90$

- Have not yet accounted for disutility of staying overnight at the airport, etc.

## Random variables

- Random Variable:
- Basic element of probability assertions
- Similar to CSP variable, but values reflect probabilities not constraints.
- Variable: A
- Domain: $\left\{\mathrm{a}_{1}, \mathrm{a}_{2}, \mathrm{a}_{3}\right\} \quad$-- events / outcomes
- Types of Random Variables:
- Boolean random variables : \{true, false \}
- e.g., Cavity (= do I have a cavity?)
- Discrete random variables : one value from a set of values
- e.g., Weather is one of \{sunny, rainy, cloudy , snow\}
- Continuous random variables : a value from within constraints
- e.g., Current temperature is bounded by $\left(10^{\circ}, 200^{\circ}\right)$
- Domain values must be exhaustive and mutually exclusive:
- One of the values must always be the case (Exhaustive)
- Two of the values cannot both be the case (Mutually Exclusive)

## Random variables

- Example: Coin flip
- Variable = R, the result of the coin flip
- Domain = \{heads, tails, edge $\}$
- $\mathrm{P}(\mathrm{R}=$ heads $)=0.4999$
- $P(R=$ tails $)=0.4999$
$-P(R=$ edge $)=0.0002$

- Shorthand is often used for simplicity:
- Upper-case letters for variables, lower-case letters for values.
- E.g., $P(A) \quad \equiv<P(A=a 1), P(A=a 2), \ldots, P(A=a n)>$ for all $n$ values in Domain(A)
- Note: $P(A)$ is a vector giving the probability that $A$ takes on each of its $n$ values in Domain (A)
- E.g.,

$$
\begin{array}{ll}
P(a) & \equiv P(A=a) \\
P(a \mid b) & \equiv P(A=a \mid B=b) \\
P(a, b) & \equiv P(A=a \wedge B=b)
\end{array}
$$

- Two kinds of probability propositions:
- Elementary propositions are an assignment of a value to a random variable:
- e.g., Weather = sunny; e.g., Cavity = false (abbreviated as $\neg$ cavity)
- Complex propositions are formed from elementary propositions and standard logical connectives :
- e.g., Cavity = false V Weather = sunny

## Probability

- $P(a)$ is the probability of proposition " $a$ "
- E.g., P(it will rain in London tomorrow)
- The proposition "a" is actually true or false in the real world
- $P(a)$ is our degree of belief that proposition " $a$ " is true in the real world
- $\mathrm{P}(\mathrm{a})=$ "prior" or marginal or unconditional probability
- Assumes no other information is available
- Axioms of probability:
- $0<=\mathrm{P}(\mathrm{a})<=1$
- $P($ NOT(a)) $=1-P(a)$
- $P$ (true) $=1$
- $P$ (false) $=0$
$-P(a O R b)=P(a)+P(b)-P(a$ AND $b)$
- Any agent that holds degrees of beliefs that contradict these axioms will act sub-optimally in some cases
- e.g., de Finetti (R\&N pp. 489-490) proved that there will be some combination of bets that forces such an unhappy agent to lose money every time.
- Rational agents cannot violate probability theory.

## Interpretations of probability

- Relative Frequency: Usually taught in school
- $\mathrm{P}(a)$ represents the frequency that event $a$ will happen in repeated trials.
- Requires event $a$ to have happened enough times for data to be collected.
- Degree of Belief: A more general view of probability
- $\mathrm{P}(a)$ represents an agent's degree of belief that event $a$ is true.
- Can predict probabilities of events that occur rarely or have not yet occurred.
- Does not require new or different rules, just a different interpretation.
- Examples:
- a = "life exists on another planet"
- What is $\mathrm{P}(\mathrm{a})$ ? We all will assign different probabilities
- $a=$ "California will secede from the US"
- What is $\mathrm{P}(\mathrm{a})$ ?
- $a=$ "over $50 \%$ of the students in this class will get A's"
- What is $\mathrm{P}(\mathrm{a})$ ?

## Concepts of probability

- Unconditional Probability
- P(a), the probability of " $a$ " being true, or $\mathbf{P ( a = T r u e )}$
- Does not depend on anything else to be true (unconditional)
- Represents the probability prior to further information that may adjust it (prior)
- Also sometimes "marginal" probability (vs. joint probability)
- Conditional Probability
- P(a|b), the probability of "a" being true, given that " $b$ " is true
- Relies on " $b$ " = true (conditional)
- Represents the prior probability adjusted based upon new information "b" (posterior)
- Can be generalized to more than 2 random variables:
- e.g. P(a|b, c, d)

## We often use comma to abbreviate AND.

- Joint Probability
- $\mathbf{P}(\mathbf{a}, \mathrm{b})=\mathbf{P}(\mathbf{a} \wedge \mathbf{b})$, the probability of "a" and " $b$ " both being true
- Can be generalized to more than 2 random variables:
- e.g. $P(a, b, c, d)$

## Probability Space $P(A)+P(\neg A)=1$

## Entire Sample Space: $P(S)=1$

Area $=$ Probability of Event

# AND Probability <br> $P(A, B)=P(A \wedge B)=P(A)+P(B)-P(A \vee B)$ 

Entire Sample Space: $P(S)=1$

Area $=$ Probability of Event

# OR Probability $P(A \vee B)=P(A)+P(B)-P(A \wedge B)$ 

Entire Sample Space: $P(S)=1$

Area $=$ Probability of Event

# Conditional Probability $P(A \mid B)=P(A, B) / P(B)=P(A \wedge B) / P(B)$ 

Entire Sample Space: $P(S)=1$

Area $=$ Probability of Event

## Product Rule <br> $$
P(A, B)=P(A \mid B) P(B)
$$

Entire Sample Space: $P(S)=1$

Area $=$ Probability of Event

## Using the Product Rule

- Applies to any number of variables:
$-P(a, b, c)=P(a, b \mid c) P(c)=P(a \mid b, c) P(b, c)$
$-P(a, b, c \mid d, e)=P(a \mid b, c, d, e) P(b, c \mid d, e)$
- Factoring: (AKA Chain Rule for probabilities)
- By the product rule, we can always write:

$$
P(a, b, c, \ldots y, z)=P(a \mid b, c, \ldots y, z) P(b, c, \ldots y, z)
$$

We often use comma to abbreviate AND.

- Repeating this idea, we can completely factor $\mathrm{P}(\mathrm{a}, \mathrm{b}, \ldots, \mathrm{z})$ :

$$
\begin{aligned}
& P(a, b, c, \ldots y, z) \\
& \quad=P(a \mid b, c, \ldots y, z) P(b \mid c, \ldots y, z) P(c \mid \ldots y, z) \ldots P(y \mid z) P(z)
\end{aligned}
$$

- These relationships hold for any ordering of the variables

## Examples of complete Factoring Using the Product Rule (can use any variable ordering)

- $P(a, b)=P(a \mid b)(b)$
- $P(a, b, c)=P(a \mid b, c) P(b, c)$

$$
=P(a \mid b, c) P(b \mid c) P(c) \quad<=\text { complete factoring }
$$

- $P(a, b, c, d)=P(a \mid b, c, d) P(b, c, d)$

$$
=P(a \mid b, c, d) P(b \mid c, d) P(c, d)
$$

$$
=P(a \mid b, c, d) P(b \mid c, d) P(c \mid d) P(d) \quad<=\text { complete factoring }
$$

- $P(a, b, c, d, e)=P(a \mid b, c, d, e) P(b, c, d, e)$

$$
\begin{aligned}
& =P(a \mid b, c, d, e) P(b \mid c, d, e) P(c, d, e) \\
& =P(a \mid b, c, d, e) P(b \mid c, d, e) P(c \mid d, e) P(d, e) \\
& =P(a \mid b, c, d, e) P(b \mid c, d, e) P(c \mid d, e) P(d \mid e) P(e) \quad<=\text { complete }
\end{aligned}
$$

# Sum Rule <br> $\mathrm{P}(\mathrm{A})=\Sigma_{\mathrm{B}, \mathrm{C}} \mathrm{P}(\mathrm{A}, \mathrm{B}, \mathrm{C})=\Sigma_{\mathrm{b} \in \mathrm{B}, \mathrm{c} \in \mathrm{C}} \mathrm{P}(\mathrm{A}, \mathrm{b}, \mathrm{c})$ 

Entire Sample Space: $\mathrm{P}(\mathrm{S})=1$

Area $=$ Probability of Event

## Using the Sum Rule

- We can marginalize variables out of any joint distribution by simply summing over that variable:
- $P(b)=\Sigma_{a} \Sigma_{c} \Sigma_{d} P(a, b, c, d)$
$-P(a, d)=\Sigma_{b} \Sigma_{c} P(a, b, c, d)$

> We often use comma to abbreviate AND.

- For Example: Determine probability of catching a fish
- Given a set of probabilities P(CatchFish, Day, Lake)
- Where:
- CatchFish $=$ \{true, false\}
- Day=
\{mon, tues, wed, thurs, fri, sat, sun\}
- Lake = \{blue lake, ralph lake, crystal lake\}
- Need to find P(CatchFish = True):
- $P($ CatchFish $=$ true $)=\Sigma_{\text {day }} \Sigma_{\text {lake }} P($ CatchFish $=$ true, day, lake $)$

# Bayes' Rule $P(B \mid A)=P(A \mid B) P(B) / P(A)$ 

Entire Sample Space: $P(S)=1$

Area $=$ Probability of Event

## Derivation of Bayes' Rule

- Start from Product Rule:

$$
-P(a, b)=P(a \mid b) P(b)=P(b \mid a) P(a)
$$

- Isolate Equality on Right Side:
$-P(a \mid b) P(b)=P(b \mid a) P(a)$
- Divide through by $\mathbf{P ( b ) : ~}$
- $P(a \mid b)=P(b \mid a) P(a) / P(b) \quad<--B a y e s^{\prime}$ Rule
- "Bayes' rule underlies most modern approaches to uncertain reasoning in Al systems."-R\&N p. 9

## Who's Bayes?

- Reverend Thomas Bayes (c. 1701-1761) was an English minister and mathematician. His ideas have created much controversy and debate among statisticians....
- The paper that describes Bayes' Theorem (or Bayes' Rule) was discovered in his office after his death. Allegedly, he was trying to prove the existence of God by mathematics; though this is not certain and other motives also are alleged. His paper was sent to the Royal Society with a note, "Some of your members may be interested in this." It was published by, and read to, the Royal Society. Nowadays, it has given rise to an immense body of statistical and probabilistic work.

## Thomas Bayes

> Portrait purportedly of Bayes used in a 1936 book, but it is doubtful the portrait is actually of him. No earlier claimed portrait survives.

## Summary of probability rules

- Product Rule: (aka Chain Rule)
- $P(a, b)=P(a \mid b) P(b)=P(b \mid a) P(a) P r o b a b i l i t y$ of "a" and " $b$ " occurring is the "same as probability of " $a$ " occurring given " $b$ " is true, times the probability of "b" occurring.
- e.g., $\quad P($ rain, cloudy $)=P($ rain $\mid$ cloudy $) * P(c l o u d y)$
$-P(a, b, c, \ldots, y, z)=P(a \mid b, c, \ldots, y, z) P(b \mid c, \ldots, y, z) \ldots P(y \mid z) P(z)$
- Sum Rule: (aka Law of Total Probability)
$-\mathrm{P}(\mathrm{a})=\Sigma_{\mathrm{b}} \mathrm{P}(\mathrm{a}, \mathrm{b})=\Sigma_{\mathrm{b}} \mathrm{P}(\mathrm{a} \mid \mathrm{b}) \mathrm{P}(\mathrm{b}), \quad$ where B is any random variable
- Probability of "a" occurring is the same as the sum of all joint probabilities including the event, provided the joint probabilities represent all possible events.
- Can be used to "marginalize" out other variables from probabilities, resulting in prior probabilities also being called marginal probabilities.
- e.g., $\quad P($ rain $)=\Sigma_{\text {windspeed }} P($ rain, Windspeed $)$
where Windspeed $=\{0-10 \mathrm{mph}, 10-20 \mathrm{mph}, 20-30 \mathrm{mph}$, etc. $\}$
- Bayes' Rule:
- $P(b \mid a)=P(a \mid b) P(b) / P(a)$
- Acquired from rearranging the product rule.
- Allows conversion between conditionals, from $P(b \mid a)$ to $P(a \mid b)$.
- e.g.,
b = disease, $a=$ symptoms
More natural to encode knowledge as $\mathrm{P}(\mathrm{a} \mid \mathrm{b})$ than as $\mathrm{P}(\mathrm{b} \mid \mathrm{a})$.

## Full Joint Distribution

- We can fully specify a probability space by a full joint distribution:
- A full joint distribution contains a probability for every possible combination of variable values. This requires:

$$
\Pi_{\text {vars }}\left(n_{\text {var }}\right) \text { probabilities }
$$

where $\mathbf{n v a r}$ is the number of values in the domain of variable var

- E.g. $\quad P(A, B, C)$, where $A, B, C$ have 4 values each;

Full joint distribution specified by $4^{3}$ values $=64$ values

| C | C | $\mathrm{P}(\mathrm{T}, \mathrm{D}, \mathrm{C})$ |  |
| :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0.576 |
| 0 | 0 | 1 | 0.008 |
| 0 | 1 | 0 | 0.144 |
| 0 | 1 | 1 | 0.072 |
| 1 | 0 | 0 | 0.064 |
| 1 | 0 | 1 | 0.012 |
| 1 | 1 | 0 | 0.016 |
| 1 | 1 | 1 | 0.108 |

- For $\mathbf{n}$ variables each with $\boldsymbol{m}$ values, requires $\boldsymbol{m}^{\mathbf{n}}$ probabilities
- E.g., a realistic problem of 100 Boolean variables requires $>10^{30}$ probabilities (intractable)
- Using a full joint distribution, we can use the product rule, sum rule, and Bayes' rule to create any combination of joint, marginal, and conditional probabilities.

## Mareinaiprobabity

- Can fully specify a probability space by constructing a full joint distribution
- Example: dentist
- T: have a toothache
- D: dental probe catches
- C: have a cavity
- Joint distribution
- Assigns each event ( $T=t, D=d, C=c$ ) a probability
- Probabilities sum to 1.0

$$
\begin{aligned}
& \text { Law of total probability: } \\
& \qquad \begin{array}{l}
p(C=1)
\end{array}=\sum_{t, d} P(t=t, D=d, C=1) \\
& =0.008+0.072+0.012+0.108=0.20
\end{aligned}
$$

- Some value of (T,D) must occur; values are disjoint
- "Marginal probability" of C; "marginalize" or "sum over" T,D
- Early actuaries wrote row \& column totals in their probability table margins

## The effect of evidence

- Example: dentist
- T: have a toothache
- D: dental probe catches
- C: have a cavity
- Recall $p(C=1)=0.20$
- Suppose we observe $\mathrm{D}=0, \mathrm{~T}=0$ ?

$$
p(C=1 \mid D=0, T=0)=\frac{p(C=1, D=0, T=0)}{p(D=0, T=0)}
$$

Called posterior probabilities or conditional probabilities

$$
=\frac{0.008}{0.576+0.008}=0.012
$$

- Observe $\mathrm{D}=1, \mathrm{~T}=1$ ?

$$
p(C=1 \mid D=1, T=1)=\frac{0.108}{0.016+0.108}=0.871
$$

## The effectofevidence

- Example: dentist
- T: have a toothache
- D: dental probe catches
- C: have a cavity
- Combining these rules:

$$
\begin{aligned}
& \nearrow \\
& p(T=1)=0.20
\end{aligned}
$$

## connouting posteriors

- Sometimes it is easiest to normalize last

$$
p(C \mid T=1)=\frac{1}{p(T=1)} p(C, T=1) \propto p(C, T=1)=\sum_{d} p(C, d, T=1)
$$

| T | D | C | $\mathrm{P}(\mathrm{T}, \mathrm{D}, \mathrm{C})$ |
| :--- | :--- | :--- | :---: |
| 0 | 0 | 0 | 0.576 |
| 0 | 0 | 1 | 0.008 |
| 0 | 1 | 0 | 0.144 |
| 0 | 1 | 1 | 0.072 |
| 1 | 0 | 0 | 0.064 |
| 1 | 0 | 1 | 0.012 |
| 1 | 1 | 0 | 0.016 |
| 1 | 1 | 1 | 0.108 |

$$
\text { Assign } \mathrm{T}=1
$$

| $\mathbf{D} C$ |  | $F(D, C)$ |
| :--- | :--- | :--- |
| 0 | 0 | 0.064 |
| 0 | 1 | 0.012 |
| 1 | 0 | 0.016 |
| 1 | 1 | 0.108 |

Sum over D

Normalize

- The normalizing constant $\alpha$ is used to abbreviate normalization

$$
p(C / T=1)=\alpha \Sigma_{d} p(C, d, T=1)=\Sigma_{d} p(C, d, T=1) / p(T=1)
$$

## Indenendence

- $X, Y$ independent:
- $p(X=x, Y=y)=p(X=x) p(Y=y) \quad$ for all $x, y$
- Shorthand: $p(X, Y)=P(X) P(Y)$
- Equivalent: $p(X \mid Y)=p(X)$ or $p(Y \mid X)=p(Y) \quad$ (if $p(Y), p(X)>0)$
- Intuition: knowing $X$ has no information about $Y$ (or vice versa) Independent probability distributions:

$$
P(A, B, C)=P(A) * P(B) * P(C)
$$

| $A$ |  |
| :--- | :--- |
| 0 | $P(A)$ |
| 1 | 0.4 |

| $B$ |  |
| :---: | :---: |
| 0 | $P(B)$ |
| 1 | 0.7 |

| $C$ | $P(C)$ |
| :---: | :---: |
| 0 | 0.1 |
| 1 | 0.9 |

Joint:

This property can greatly reduce representation size!
Note: it is hard to "read" independence from the joint distribution.
We can "test" for it, but to do so requires a number of tests equal to the size of the joint distribution.

| $A$ | $B$ | $C$ | $P(A, B, C)$ |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | $.4^{*} .7^{*} .1=.028$ |
| 0 | 0 | 1 | $.4^{*} .7^{*} .9=.252$ |
| 0 | 1 | 0 | $.4^{*} .3^{*} .1=.012$ |
| 0 | 1 | 1 | $.4^{*} .3^{*} .9=.108$ |
| 1 | 0 | 0 | $.6^{*} .7^{*} .1=.042$ |
| 1 | 0 | 1 | $.6^{*} .7^{*} .9=.378$ |
| 1 | 1 | 0 | $.6^{*} .3^{*} .1=.018$ |
| 1 | 1 | 1 | $.6^{*} .3^{*} .9=.162$ |

We may omit leading zeroes to save space and effort.

## conditionatindenencence

- $X, Y$ independent given $Z$
$-p(X=x, Y=y \mid Z=z)=p(X=x \mid Z=z) p(Y=y \mid Z=z) \quad$ for all $x, y, z$
- Equivalent: $p(X \mid Y, Z)=p(X \mid Z)$ or $p(Y \mid X, Z)=p(Y \mid Z)$ 0)
- Intuition: X has no additional info about Y beyond Z 's
- Example
$X=$ height
$Y=$ reading ability
$Z=$ age
Height and reading ability are dependent (not independent), but are conditionally independent given age

## Conditional Independence

Symptom 1 and symptom 2 are conditionally independent, given group.
But clearly, symptom 1 and 2 are marginally dependent, unconditionally.

## Conditional Independence Example:

- $X, Y$ independent given $Z$
- $p(X=x, Y=y \mid Z=z)=p(X=x \mid Z=z) p(Y=y \mid Z=z) \quad$ for all $x, y, z$
- A box contains two coins: one regular coin, $P$ (heads) $=.5$, and one fake two-headed coin, $P$ (heads) $=1$. I choose a coin at random and toss it twice. Define the following events.
- A = First coin toss results in heads
- $B=$ Second coin toss results in heads
- $\mathrm{C}=$ Coin 1 (regular) has been selected
- $P(A \wedge B)=5 / 8 \neq P(A) P(B)=9 / 16$, so $A$ and $B$ are not independent
- Event A makes it more likely I selected the two-headed coin, which makes Event B more likely. Knowing Event A gives information about Event B.
- $P(A \wedge B / C)=1 / 4=P(A / C) P(B / C)$, so $A$ and $B$ are independent given $C$
- Given $C$, knowing Event $A$ gives no information about Event $B$.

## Conditional Independence Example:

- $X, Y$ independent given $Z$
- $p(X=x, Y=y \mid Z=z)=p(X=x \mid Z=z) p(Y=y \mid Z=z) \quad$ for all $x, y, z$
- Consider two brothers John and Joseph, both having a genetic disease. These two events are dependent as they are brothers.
- However, given the condition that Joseph is an adopted son of the family makes the events conditionally independent.

## Conditional Independence Example:

- $X, Y$ independent given $Z$
- $p(X=x, Y=y \mid Z=z)=p(X=x \mid Z=z) p(Y=y \mid Z=z) \quad$ for all $x, y, z$
- Rain causes both increased umbrella usage and worsened road conditions. These events are not independent because seeing lots of umbrellas makes worsened road conditions more likely.
- However, given the condition that it is raining makes the events conditionally independent. Once you know it is raining, seeing umbrellas tells you nothing more about road conditions.

## Conditional Independence

- $X, Y$ independent given $Z$
- $p(X=x, Y=y \mid Z=z)=p(X=x \mid Z=z) p(Y=y \mid Z=z) \quad$ for all $x, y, z$
- Equivalent: $p(X \mid Y, Z)=p(X \mid Z)$ or $p(Y \mid X, Z)=p(Y \mid Z)$
- Intuition: $X$ has no additional info about $Y$ beyond $Z$ 's
- Example: Dentist Conditionally independent distributions:

| D |  |  | C |
| :--- | :--- | :--- | :--- |
|  | $\mathrm{P}(\mathrm{T}, \mathrm{D}, \mathrm{C})$ |  |  |
| 0 | 0 | 0 | 0.576 |
| 0 | 0 | 1 | 0.008 |
| 0 | 1 | 0 | 0.144 |
| 0 | 1 | 1 | 0.072 |
| 1 | 0 | 0 | 0.064 |
| 1 | 0 | 1 | 0.012 |
| 1 | 1 | 0 | 0.016 |
| 1 | 1 | 1 | 0.108 |

- $P(T, D \mid C)=P(T \mid C) * P(D \mid C)$

Again, hard to "read" from the joint probabilities; only from the conditional probabilities.

Like independence, can greatly reduce representation size!

We may omit leading zeroes to save space and effort.

| $C$ |  | $P(T \mid C)$ |
| :---: | :---: | :---: |
| 0 | 0 | .9 |
| 0 | 1 | .4 |
| 1 | 0 | .1 |
| 1 | 1 | .6 |

Conditional probabilities:

| Joint: | T | D | c | P(T, D $\mid$ C) |
| :---: | :---: | :---: | :---: | :---: |
|  | 0 | 0 | 0 | . 9 * $8=.72$ |
|  | 0 | 0 | 1 | . 4 *. $1=.04$ |
|  | 0 | 1 | 0 | . $9 * .2=.18$ |
|  | 0 | 1 | 1 | . $4 * .9=.36$ |
|  | 1 | 0 | 0 | . 1 * $8=.08$ |
|  | 1 | 0 | 1 | . $6 * .1=.06$ |
|  | 1 | 1 | 0 | . 1 * . $2=.02$ |
|  | 1 | 1 | 1 | . 6 * 9 = . 54 |

## Conditional Independence

- Formal Definition:
- 2 random variables $A$ and $B$ are conditionally independent given $C$ iff: $P(a, b \mid c)=P(a \mid c) P(b \mid c), \quad$ for all values $a, b, c$
- Informal Definition:
- 2 random variables $A$ and $B$ are conditionally independent given $C$ iff: $P(a \mid b, c)=P(a \mid c) \quad O R \quad P(b \mid a, c)=P(b \mid c), \quad$ for all values $a, b, c$
- $P(a \mid b, c)=P(a \mid c)$ tells us that learning about $b$, given that we already know $c$, provides no change in our probability for $a$, and thus $b$ contains no information about a beyond what c provides.
- Naïve Bayes Model:
- Often a single variable can directly influence a number of other variables, all of which are conditionally independent, given the single variable.
- E.g., $k$ different symptom variables $X_{1}, X_{2}, \ldots X_{k}$, and $C=$ disease, reducing to:

$$
P\left(X_{1}, X_{2}, \ldots . X_{K} \mid C\right)=\Pi P\left(X_{i} \mid C\right)
$$

## Full Joint vs Conditional Independence

- Example : 4 Binary Random Variable (A,B,C,D)
- Full Joint Probability Table
- 1 Table with 16 rows
- Conditional Independence
- $P(A, B, C, D)=P(A) P(B \mid A) P(C \mid A, B) P(D \mid A, B, C)$ (no saving yet..)
- if... $P(D \mid A, B)=P(C \mid A), P(D \mid A, B, C)=P(D \mid A)[$ Naïve Bayes Model]
$-P(A, B, C, D)=P(A) P(B \mid A) P(C \mid A) P(D \mid A)$
-4 Tables. With at most 4 rows
- If we had N Binary Random Variables
- Full Joint Probability Table
- 1 Table with $2^{\wedge}(\mathrm{N})$ Rows; $\mathrm{N}=100,2^{\wedge} 100$ ~= $10^{\wedge} 30$
- Naïve Bayes Model (Conditional Independence)
- N tables with at most 4 rows!

## Conclusions...

- Representing uncertainty is useful in knowledge bases.
- Probability provides a framework for managing uncertainty.
- Using a full joint distribution and probability rules, we can derive any probability relationship in a probability space.
- Number of required probabilities can be reduced through independence and conditional independence relationships
- Probabilities allow us to make better decisions by using decision theory and expected utilities.
- Rational agents cannot violate probability theory.
