# Machine Learning and Data Mining

## Nearest neighbor methods

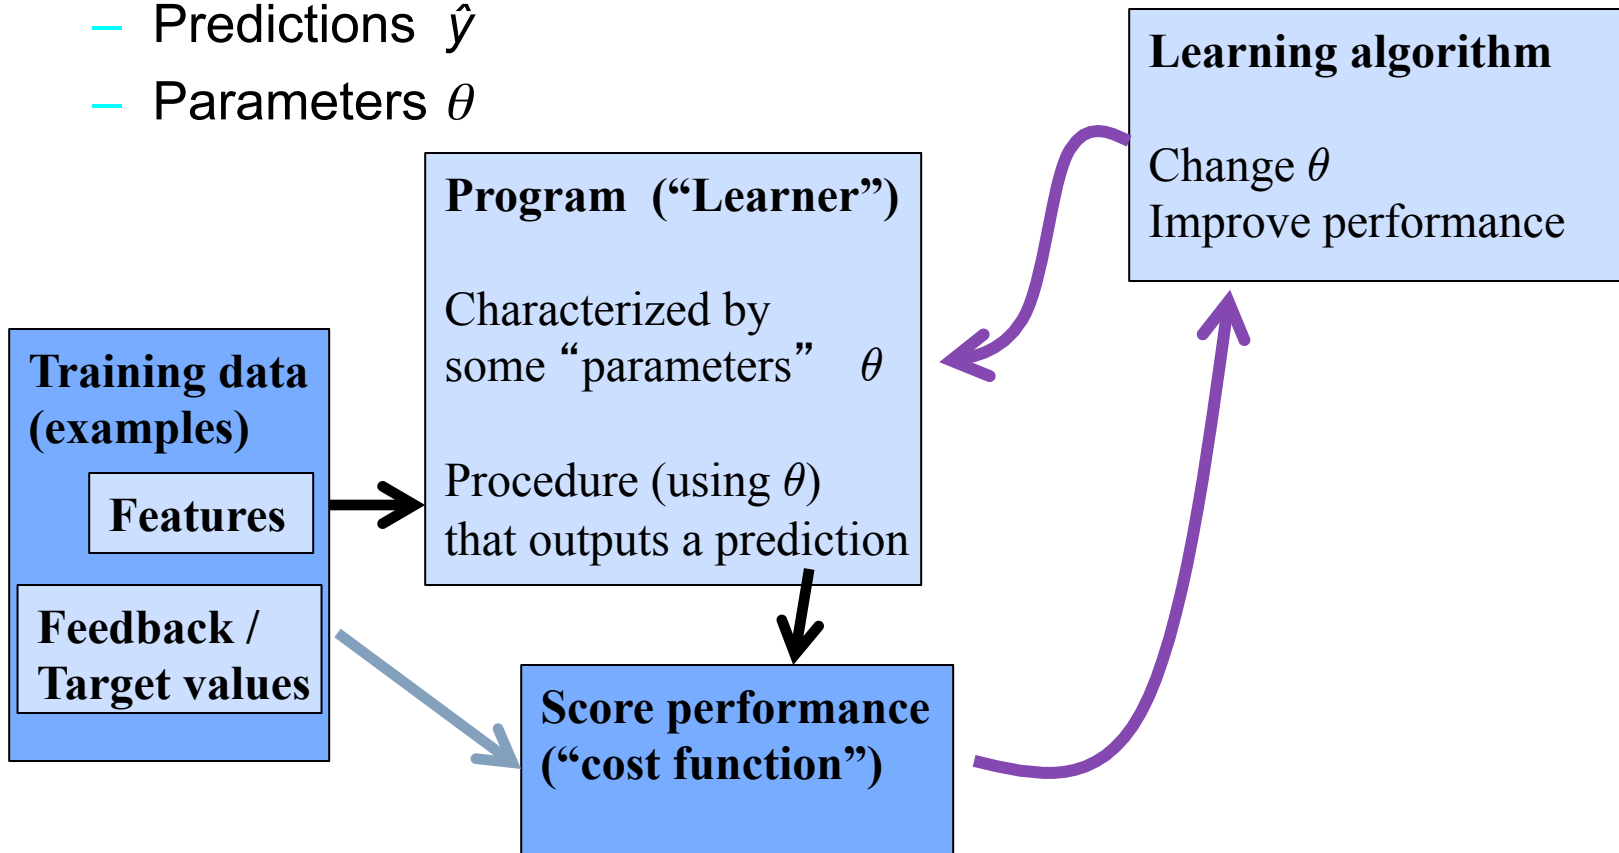

Prof. Alexander Ihler

# Supervised learning

- Notation

- Features  $x$
- Targets  $y$
- Predictions  $\hat{y}$
- Parameters  $\theta$

# Regression; Scatter plots

- Suggests a relationship between  $x$  and  $y$
- Regression: given new observed  $x^{(new)}$ , estimate  $y^{(new)}$

# Nearest neighbor regression

## “Predictor”:

Given new features:  
Find nearest example  
Return its value

- Find training datum  $x^{(i)}$  closest to  $x^{(new)}$ ; predict  $y^{(i)}$

# Nearest neighbor regression

## **“Predictor”:**

Given new features:  
Find nearest example  
Return its value

- Find training datum  $x^{(i)}$  closest to  $x^{(new)}$ ; predict  $y^{(i)}$
- Defines an (implicit) function  $f(x)$
- “Form” is piecewise constant

# Nearest neighbor classifier

**“Predictor”:**

Given new features:  
Find nearest example  
Return its value

# Nearest neighbor classifier

**“Predictor”:**

Given new features:  
Find nearest example  
Return its value

**“Closest” training  $x$ ?**

Typically Euclidean distance:

$$d(x, x') = \sqrt{\sum_i (x_i - x'_i)^2}$$

## Nearest neighbor methods: K-Nearest Neighbors

Prof. Alexander Ihler

# K-Nearest Neighbor (kNN) Classifier

- Find the k-nearest neighbors to  $\underline{x}$  in the data
  - i.e., rank the feature vectors according to Euclidean distance
  - select the k vectors which have smallest distance to  $\underline{x}$
- Regression
  - Usually just average the y-values of the k closest training examples
- Classification
  - ranking yields k feature vectors and a set of k class labels
  - pick the class label which is most common in this set (“vote”)
  - classify  $\underline{x}$  as belonging to this class
  - Note: for two-class problems, if k is odd (k=1, 3, 5, ...) there will never be any “ties”
- “Training” is trivial: just use training data as a lookup table, and search to classify a new datum

# kNN Decision Boundary

- Piecewise linear decision boundary
- Increasing  $k$  “simplifies” decision boundary
  - Majority voting means less emphasis on individual points

$K = 1$

$K = 3$

# kNN Decision Boundary

- Recall: piecewise linear decision boundary
- Increasing  $k$  “simplifies” decision boundary
  - Majority voting means less emphasis on individual points

$K = 5$

$K = 7$

# kNN Decision Boundary

- Recall: piecewise linear decision boundary
- Increasing  $k$  “simplifies” decision boundary
  - Majority voting means less emphasis on individual points

$K = 25$

# Error rates and K

K=1? Zero error!  
Training data have been memorized...

Best value of K

# Complexity & Overfitting

- Complex model predicts all training points well
- Doesn't generalize to new data points
- $K=1$  : perfect memorization of examples (complex)
- $K=M$  : always predict majority class in dataset (simple)
- Can select  $K$  using validation data, etc.

# K-Nearest Neighbor (kNN) Classifier

- Theoretical Considerations
  - as k increases
    - we are averaging over more neighbors
    - the effective decision boundary is more “smooth”
  - as N increases, the optimal k value tends to increase
  - k=1, m increasing to infinity : error < 2x optimal
- Extensions of the Nearest Neighbor classifier
  - weighted distances
    - e.g., if some of the features are more important
    - e.g., if features are irrelevant
$$d(x, x') = \sqrt{\sum_i w_i (x_i - x'_i)^2}$$
  - fast search techniques (indexing) to find k-nearest neighbors in d-space

# Summary

---

- K-nearest neighbor models
  - Classification (vote)
  - Regression (average or weighted average)
- Piecewise linear decision boundary
  - How to calculate
- Test data and overfitting
  - Model “complexity” for knn
  - Use validation data to estimate test error rates & select k
